

# Measurement of the single top t-channel cross section at CMS

## GK Workshop Bad Liebenzell 2012

Steffen Röcker | 10.10.2012

INSTITUT FÜR EXPERIMENTELLE KERNPHYSIK

# Single top production

- $\blacksquare$  Virtuality of the involved W boson  $\rightarrow$  three different production mechanisms
- t-channel and tW cross sections largely enhanced at LHC due to gluon splitting
- *t*-channel and *tW* depend on b-quark PDF (up to 4%  $\Delta \sigma$ )
- Largest cross section at Tevatron and LHC: t-channel

# Single top - history and motivation

- Single top quark production first discovered in 2009 at Tevatron by CDF and DØ
- Discovery in s+t-channel after long and difficult search
- Rediscovery of t-channel in 2011 at LHC with first data
- Can now be studied in detail at LHC

Interesting properties:

- Allows direct measurement of CKM matrix element  $|V_{tb}|$
- Sensitive to b quark PDF
- Wtb coupling enables tests of V–A structure, anomalous couplings
- Allows study of top quark polarization
- Background for Higgs/SUSY and search for new physics (4th generation,  $H^+$ ,  $W^{'}$ )

# Top quark decay

- Top quark decays immediately due to high mass / large width
- Top quark decays into W boson and b quark (SM: BR  $\approx$  100%)
- W boson from top-quark decay further decays into charged lepton and neutrino (BR  $\approx$  32%), here only muon and electron channel
- Spin information passed to decay products

## **Event selection**

- Muon (electron+b-jet) trigger  $\rightarrow$  data set 1.17/fb (1.56/fb)
- 1 isolated muon (electron) with  $p_T > 20(30)$  GeV/c and  $|\eta| < 2.1$  (2.5)
- Veto electrons (muons) and loose muons (electrons) in muon (electron) decay channel
- MTW > 50 GeV/ $c^2$  ( $E_T^{miss}$  > 35 GeV/ $c^2$ ) to suppress QCD

- 2,3 or 4 jets with  $p_T$  > 30 GeV/c and  $|\eta|$  < 4.5
- 0, 1 or  $\geq$  2 jets with b-tag (0.1% mistag rate)

# **CMS** detector

 Single top analyses need information from all detector subsystems to reconstruct (forward) jets, leptons, and missing transverse energy (E<sup>miss</sup><sub>T</sub>)

# Event Display - $\rho - z$ plane

Karbruhe Institute of Technology

# Top quark reconstruction

- Reconstructed from detector: jets, leptons, E<sup>miss</sup><sub>T</sub>
- Top quark candidate reconstructed from W boson and b-tagged jet
- W boson from lepton and  $E_T^{miss}$ :  $p_{z,\nu}$  from  $E_T^{miss}$  by constraint on W boson mass
  - Two real solutions: Choose the one with smallest  $|p_{z,\nu}|$
  - Imaginary solution: Minimal variation of  $E_T^{miss}$  so that  $M_T^W = M_W$
- Assign b-tagged jet to top quark decay
  - Assignment of top quark correct in approx. 88% of cases (MC studies)

# Backgrounds

- Contribution from background processes after selection:
  - Single Top: *s*-channel, *tW*
  - W+jets
  - Top quark pair production tt
  - Z+jets
  - Diboson (WW, WZ, ZZ)
  - QCD multijet

- Main backgrounds: W+jets and top quark pair production  $t\bar{t}$
- $\blacksquare$  QCD multijet background difficult to model, MC statistics very small  $\rightarrow$  data driven estimation

# Data driven background estimation

- QCD multijet distribution extracted from orthogonal data set:
- Muon channel:
  - Invert relative isolation cut
- Electron channel:
  - Anti-Electron ID
     (2 out of 3 criteria must not be fulfilled)
- Orthogonal selection has been checked in MC
- Fit to transverse mass of W boson (MTW) /  $E_T^{miss}$  before cut to extract shape and rate  $F(x) = a \cdot S(x) + b \cdot B(x)$

# **Discriminating variables**

- Pseudorapidity of light quark mostly in forward region
- Other variables alone: not much separation power
- lacksquare  $\to$  Use a multivariate technique

# **Neural network**

- Karbruhe Institute of Technology
- Artificial neural networks (NN) modeled after biological neural networks
- Multiple nodes with nonlinear activation function in three or more layers, each node connected to every node in the next layer with specific weight
- The network learns by minimizing an error function and changing the weights (Supervised learning, backpropagation)

### NeuroBayes:

- 3-layer feedforward network
- Robust preprocessing of input variables (Decorrelation, transformation to Gaussian)
- Spline-fit to variables to be robust against statistical fluctuations or noise

# Neural network - input variables

- Detailed studies of multiple variables
- Only use well modeled variables, i.e. those with good KS test values in control region
- Network rejects variables with low significance
- 37 variables in muon channel
   38 variables in electron channel
- Most important variables: light quark η, H<sub>T</sub>, M<sub>jet1,jet2</sub>

#### correlation matrix of input variables

# Neural network - training

- Signal/background ratio 50:50 (*t*-channel vs *tt*, *W*+jets, *Z*+jets)
- Network can separate signal and background
- Purity increases with discriminator output

# Neural network - discriminator in background region

Discriminator output well modeled in  $t\bar{t}$  enriched background region

## Neural network - discriminator in signal region

# Statistical inference

Bayesian method

$$p(\mu| ext{data}) \propto \int p'( ext{data}|\mu,ec{ heta}) \cdot \pi(\mu)\pi(ec{ heta}) \, \mathrm{d}ec{ heta}$$

- Impact of systematic effects marginalized as nuisance parameters (JER, JES, b-tagging, ...)
- Influence of theoretical uncertainties studied separately, not marginalized (Renormalization/factorization (Q<sup>2</sup> scale), matching, PDF, different signal generator)
- Integration via Markov Chain Monte Carlo (MCMC)
- Statistical framework: http://www.theta-framework.org
- Cross section for electrons, muons:

$$\sigma_{t-ch.} = 69.7^{+7.2}_{-7.0} \text{ (stat. + syst. + lum.)} \pm 3.6 \text{ (theor.) pb}$$
(muons)  
$$\sigma_{t-ch.} = 65.1^{+9.2}_{-8.9} \text{ (stat. + syst. + lum.)} \pm 3.5 \text{ (theor.) pb}$$
(electrons)

and combined:

$$\sigma_{t-ch.} = 68.1 \pm 4.1 \text{ (stat.)} \pm 3.4 \text{ (syst.)}^{+3.3}_{-4.3} \text{ (theor.)} \pm 1.5 \text{ (lum.) pb}$$

# Combination

This measurement is combined with two other measurements:

- Template fit to light quark  $\eta$
- W+jets background data driven
- One analysis bin (2 jets 1 tag)

- BDT analysis (Aachen)
  - MVA analysis (BDT)
  - Bayesian method } same as NN
  - Multiple analysis bins

All three analyses employ the same selection

Correlation is estimated by dicing toys

# Combination - Result

Combining all three analyses with BLUE yields a cross section of

$$\sigma_{t-ch.} = \boxed{67.2 \pm 6.1 \text{ pb}} = 67.2 \pm 3.7 \text{ (stat.)} \pm 3.0 \text{ (syst.)} \pm 3.5 \text{ (theor.)} \pm 1.5 \text{ (lum.) pb}$$

- with a relative uncertainty of 9.1%
- Published in TOP-011-021 (arXiv:1209.4533), submitted to JHEP

# Combination - Estimation of $|V_{tb}|$

- Under the assumption that  $|V_{tb}|^2 \gg |V_{td}|^2 + |V_{ts}|^2$ and  $|V_{tb}| = 1$  for  $\sigma_{t-ch.}^{th}$
- One can extract  $|V_{tb}|$  from the cross section measurement

$$V = egin{pmatrix} V_{ud} & V_{us} & V_{ub} \ V_{cd} & V_{cs} & V_{cb} \ V_{td} & V_{ts} & V_{tb} \end{pmatrix}$$

$$|f_{L_V} V_{
m tb}| = \sqrt{rac{\sigma_{t-
m ch.}}{\sigma_{t-
m ch.}^{
m th}}} = 1.020 \pm 0.046 ~
m (exp.) \pm 0.017$$
 (theor.)

- with a possible anomalous form factor f<sub>L</sub> from BSM models
- Constraining  $|V_{tb}|$  to the interval [0, 1] and setting  $f_L = 1$  yields: (Feldman Cousins)

 $0.92 < |V_{tb}| \le 1@$  95% CL

Steffen Röcker - Measurement of the single top t-channel cross section at CMS

# Conclusion

- Measured single top t-channel cross section and  $|V_{tb}|$  with neural network analysis in multiple channels at  $\sqrt{s} = 7$  TeV
- Combination yields cross section with relative uncertainty < 10%</p>
- Most precise single top t-channel cross section measurement

• 
$$|V_{tb}| \approx 1$$
 and 0.92 <  $|V_{tb}| \leq 1$  @ 95% CL

# **Conclusion and outlook**

Conclusion:

- Measured single top t-channel cross section and  $|V_{tb}|$  with neural network analysis in multiple channels at  $\sqrt{s} = 7$  TeV
- Combination yields cross section with relative uncertainty < 10%</p>
- Most precise single top t-channel cross section measurement
- $|V_{tb}| \approx$  1 and 0.92  $< |V_{tb}| \le$  1 @ 95% CL

Outlook:

- Already recorded 15/fb at  $\sqrt{s} = 8$  TeV this year
- Detailed studies of theory possible:
  - Differential measurement in top  $p_T$  and  $\eta$
  - Polarization of top quarks

• . . .
